1 q1

The answers are m and 3

2 q2

The while loop multiplies fac by i returning it to itself then prints fac and i then increments i by one until i reaches 10.

3 q5

y^2 and x converge, however, due to imprecise float calculations, python does not see them as equal, therefore the condition for the while loop never arrives causing an infinite loop.

4 q6

a	b
3.3333199098706245e-06	3.3333333333703703e-06
3.3333199098706245e-06	3.3333111112962948e-06
3.333290806040168e-06	3.333288895185097e-06
3.333261702209711e-06	3.3332666680370083e-06
3.3332325983792543e-06	3.3332444468517854e-06
3.3332325983792543e-06	3.3332222259628356e-06
3.3332034945487976e-06	3.3332000053701526e-06
3.333174390718341e-06	3.3331777850737303e-06
3.333145286887884e-06	3.3331555650735625e-06
3.333145286887884e-06	3.333133345369644e-06

5 q7

when truncating each step in a() we get a result of 0.01
however when using b() and truncating each step we get a value of 5.00×10^{-3} ,
which is more accurate since the result from a() has a lower resolution.
